

# Extending the domain of freedom, or why Gaia is so hard to understand

---

Bruno Latour\* and Timothy M. Lenton#  
\*Sciences Po Paris; #University of Exeter  
To appear in *Critical Inquiry*

**Abstract:** In this paper, two specialists of Gaia theory, one from the humanities and the other from Earth System Science, make a sustained effort to list the misunderstandings created by those who have either rejected or accepted Gaia too readily. They argue that the uniqueness of the phenomenon and of the arguments made by James Lovelock and Lynn Margulis has been under-recognized. Neither mechanical nor organismic metaphors can render justice to the originality of Gaia. They show that the core of the discovery is to grant agency back to life forms and that Gaia is the highly complex result of their extension in space and duration in time. They conclude that Gaia is different from the concept of nature, a difference that opens a new way to look at the connection between biology and politics, which they define as extension of the domain of freedom.

“The Gaia hypothesis implies that the stable state of our planet includes man as part of, or partner in, a very democratic entity.” Lovelock 1979 p.145

Ever since Dipesh Chakrabarty has opened up the Pandora’s box of the definition of what humanity becomes at the time of the Anthropocene, the question of establishing some sort of new continuity between the domain of necessity (nature) and the domain of freedom (society) has been raised.<sup>1</sup> He is right that all the difficulties in giving political traction to ecological questions arise from such an incommensurability between long-term geological history and short-term human history. In this paper, we claim that *freedom*, understood as the *capacity to obey one’s own laws*, i.e. autonomy, could offer a common ground for ecological politics, on the condition of revising some of the commonly held views of what Gaia consists of. To do so, we wish to look in a new way at the concept of Gaia as it has been proposed by James Lovelock and Lynn Margulis, thanks to research done in natural and social science since the inception of this concept.

#### A common-sense view that is not so common

The public discourse about the state of the planet is currently in a paradoxical situation: on the one hand, everyone involved in the politics of climate accepts the idea that Earth *behaves as* a regulated system which has been dangerously pushed by human action out of its normal conditions of operation; on the other hand, the hypothesis that Earth is indeed a *self-regulating system* remains highly controversial and most people will certainly not connect the idea of Earth regulation with James Lovelock and Lynn Margulis’ “discovery” of Gaia. Thus, the common horizon of political action and moral commitment — Earth is a system put out of whack that should be brought back inside some form of order through the regulation of human activity — remains a local and disputed intellectual and scientific niche.

The reason for this paradox is that the Gaia theory has either been embraced with too much enthusiasm or rejected with too much scepticism, without unpacking its exact content. No wonder, since “order” and “regulation” are terms that pertain jointly to science and to politics. Those for whom it is obvious that there is some order in the regulation of the Earth as well as those for whom it remains a vague metaphor, might not have zoomed in on the precise ways through which Gaia was introduced. No matter if they come from philosophy or from science, they seem to have pigeonholed the

argument to suit their preconceptions of how nature is supposed to rule, rather than be sensitive to the originality of the phenomena offered for inquiry.<sup>2</sup> The result is that over half a century after its inception, it is hard to find a widely shared definition of Gaia.

There are of course good reasons for that. The first is that any new phenomenon is defined by comparison with some already familiar situation. Gaia however is a *unique phenomenon* — at least as long as we have no proof of another planet modified by life to provide some sort of baseline. So, it's no wonder that metaphors don't help much in defining Gaia: if you are happy with one version, it is sure to be wrong! You cannot zoom on its specificity by considerations on nature as a whole. Hence the many misunderstandings accumulated over the years around the idea that the Earth is “alive”, that it is an “organism”, a “superorganism”, a “machine”, a “cybernetic feedback control device”, a “spaceship”, a “body politic” and so on. Even the tamed notion of “system” is no more than a fragile simile in spite of the now common expression “Earth System Science” (ESS) — the polite euphemism sometimes used to avoid naming Gaia too directly.<sup>3</sup> Whilst there is a fairly widely held perception that Earth system science has replaced the idea of Gaia, we argue it is important to differentiate them. Specifically, Gaia originated and expanded in space and time from within a pre-existing Earth system. Strangely, defining such a phenomenon requires a sort of “negative geology” reminiscent of the apophatic ways that theologians had recourse to when trying to probe God's uniqueness!<sup>4</sup>

The second reason for the difficulty of making sense of Gaia, is that it's not clear if it's a discovery of a new phenomenon or the introduction in science as well as in philosophy of a new way to look at all *phenomena* on Earth. As Sébastien Dutreuil has shown in a meticulous inquiry of its historical development, Gaia is simultaneously a hypothesis, a testable theory, a summary of highly specific facts, a world view, and a philosophy of nature all mixed together.<sup>5</sup> Not to mention the claim made by some of its proponents

<sup>5</sup> Dutreuil, Sébastien, *Gaïa: hypothèse, programme de recherche pour le système Terre, ou philosophie de la Nature?* (Paris: Thèse de doctorat. Université de Paris I. , 2016) and for an English summary "James Lovelock's Gaia Hypothesis: "A New

that it might be a new religion or a new spirituality. This uncertainty explains the wide range of reactions triggered by any utterance of the word “Gaia”.

It is the aim of the present paper not to choose too fast what Gaia consists of because we claim that Lovelock’s & Margulis discovery might be just as unique as the object it tried to describe. In other words, Gaia might be the name of a shift in understanding of how to approach many phenomena of what was lumped together before in the notion of “nature”. This is why we two authors — one coming from social science and the other from natural science — are joining forces to keep open the possibility that we are dealing here with a change in what could be called a *world view* by which we mean a distribution of traits affecting science, as well as politics, morality and the arts. In brief, a cultural paradigm shift comparable in scope to the one introduced at the time of the scientific revolution by Galileo.

It is actually this shift in world view that justifies why we will use the name “Gaia” unapologetically in what follows – not in spite but *because* of its mythological baggage. Even though Earth System Science has been preferred by many scientists to avoid any connection with mythology and to avoid having to deal with the can of worms of evolutionary theories, we believe that “Gaia” is a distinct phenomenon and because of its several meanings, maintains some of the radicality necessary to make both science and society tackle the new “climate of history”. Although it has strictly the same etymology as “geo”, when it is used as a prefix in words like “Gaia-logy”, “Gaia-graphy”, “Gaia-chemistry” or “Gaia-politics”, it focuses attention on the uniqueness of the situation at hand – uniqueness that we believe has not attracted enough scrutiny.<sup>6</sup> What the prefix “geo” leads to downplay or ignore, “Gaia” forces us to underline again.

### Gaia theory is contemporary of the Anthropocene

To fathom Gaia’s uniqueness, it is convenient to reflect first on the historical situation in which its formulation came about. It was so peculiar that it would be a mistake to try to establish too much continuity between Gaia and earlier views of the balance or harmony of nature. The idea was born in a setting marked by the explosion of wholly new technical and

Look at Life on Earth" ... For the Life and the Earth Sciences." In *Dreamers, Romantics and Visionaries in the Life Sciences*, edited by Oren Harman and Michael Dietrich, (Chicago, Chicago University Press, 2018) pp. 272-288..

<sup>6</sup> Actually, as one of us has shown elsewhere, Gaia carries a lighter and more secular baggage than the highly complex and multi-layered notion of nature. See Latour, Bruno, *Facing Gaia. Eight Lectures on the New Climatic Regime* (Translated by Cathy Porter). (London: Polity Press, 2017).

industrial infrastructure. Not only was its formulation strictly contemporary with what was later called the Anthropocene,<sup>7</sup> but in addition, its first description by Lovelock depended fully on an analysis of how *human industry* had been able to modify the chemical balance of the Earth at a global scale.

As has been told many times by Lovelock himself and described by Dutreuil in great detail, it is because of the invention of exquisitely sensitive instruments — especially the electron capture detector — that Lovelock was able to quantify the extent of *industrial pollution* in a new way. His inventions were used to detect the global spread of anthropogenic pollutants, including DDT and later CFCs. And it was his resulting reputation for instrument design that led NASA to employ Lovelock in the design of life detection experiments for what were to become the Viking missions to Mars. As is well known, Lovelock puts his ‘eureka moment’ of discovering Gaia in 1965, whilst working for NASA at the Jet Propulsion Laboratory (Pasadena, California).<sup>8</sup> In many ways, his insight to look at the Earth as if from Mars was to extend to *all life forms* the possibility of disseminating their chemical by-products just as modern factories were doing.

In brief, Gaia was discovered through a level of human technology, and self-awareness of the planetary consequences of that technology, that coincides with the start of what has been called the Great Acceleration and is one of the dates chosen for the beginning of the Anthropocene.<sup>9</sup> So, if the concept of Gaia is unique, it is largely because it was born in the middle of the extraordinary ambiance of the post-war high technology boom and space mission.<sup>10</sup> It can almost be said that, conceptually, the Anthropocene idea *precedes* that of Gaia, even though, obviously, when the long history of the planet is told, the Anthropocene is portrayed as no more than a short episode within the deep history of Gaia.

Such an original birth might explain why the search for predecessors does not help much in clarifying the innovation. Several attempts to orient Gaia within preceding traditions of scientific thought have been fairly

misleading. Gaia is not continuous with older ideas that have maintained the idea of a *balance* or an *order* of nature. It is true that Lovelock credits James Hutton as a forerunner when Hutton talks of the Earth having the constitution of an animal which repairs itself.<sup>11</sup> But what Hutton was describing was the cycling of sedimentary rocks, without any particular agency for life, or any real notion of history except endless cycles. As we discuss below, his choice of an animal metaphor – a crude reuse of the old image of the body politic – is wholly inappropriate for Gaia.

Even though Margulis was fond of seeing Wladimir Vernadsky as a forerunner, Lovelock has never agreed with this, and we concur. Whilst Vernadsky brings all life forms within one big homogeneous sphere – the biosphere – he gives them no agency whatsoever, such that any organism could be replaced by any other.<sup>12</sup> Furthermore, the system has no more history than with Hutton.<sup>13</sup> Historians are fond of continuity and of discovering precursors and it is often true that reading Alexander von Humboldt or Vernadsky is reminiscent of Lovelock, but, as is well known, precursors are only discovered *after* their successors who retrospectively shed a new light on discoveries that had a different meaning.

By contrast with those precursors, the novelty introduced in the notion of Earth by the joint efforts of Lovelock and Margulis consists in granting *historicity and agency to all life forms*, that is, in attributing to the life forms themselves the task of creating the conditions for lasting in time and expanding in space. It is in that sense that they can be said “to obey their own laws”. What is especially telling is that Lovelock and Margulis succeeded in doing so because they both took the problem of the planet at two diametrically opposite scales — the largest planetary view for Lovelock, the

<sup>12</sup> See for instance at the end of *Biosphere*: “Life remains unalterable in its essential traits throughout all geological times and change only in form. All the vital films (plankton, bottom and soil) and all the vital concentrations (littoral, sargassic, and fresh water) have always existed.” Vernadsky, Wladimir I., *The Biosphere* (Translated by David B. Langmuir) with a Foreword by Jacques Grinevald) (Copernicus, 1998) p.148-149.

<sup>13</sup> Perhaps the closest forerunner to Gaia is Alfred Redfield’s work on the ‘biological control of chemical factors in the environment’, which at least grasps a cybernetic view where living agents maintain conditions preferable to them. Redfield, Alfred. “The Biological Control of Chemical Factors in the Environment.” *American Scientist* 46, no. 3 (1958): 205-21.

oldest and smallest cellular view for Margulis.<sup>14</sup> In doing so, they established a clear break with older notions of order and regulation of the planet.

Earlier notions of nature were always situating life forms *inside* a larger frame. Whatever the name given to such a frame — God’s providential dispensation, neo-darwinist natural selection, strictly mechanistic laws of nature, ecological systems, biosphere — it was from this larger frame that life forms had to get their limits and their definitions. They were not supposed to generate their own world, not to participate in anything like a history. Strictly speaking, life forms had no real agency compared to the frame that determined the order of nature. But with Lovelock & Margulis’ Gaia there is *no other order*, and certainly *no superior order* than what those intertwined agents have been producing through their entanglements.<sup>15</sup> This is why we believe that the best way to clarify such a shift in world view consists in *resisting* the addition of any supplementary frame. To be sure, as we shall see at the end, there is an order in Gaia that has political consequences, but it is not the same conception of order implied by the previous concept of nature divided from that of society. Such is the line we will follow in the rest of this paper.

### Using all means available to trace a portrait of Gaia

The uniqueness of the concept explains the multiplicity of versions given by Lovelock through his long writing career, multiplicity that, to be fair, accounts for some of the confusion. His hesitations go so far that Lovelock often presents Gaia as an intuition, an invention, which defies linear logical description. He explicitly likens his realisation of Gaia to his process of inventing technological instruments, which achieve their desired function, but without him being able to explain precisely how they work.<sup>16</sup> Although this appeal to technical invention by contrast with a scientific explanation

---

<sup>14</sup> A connection well summarized by Margulis: “The conclusion is inescapable: geophysicists and atmospheric scientists must study biology and biologists must know something of geophysics and atmospheric science. For too long, we have had atmospheric chemists wondering ‘Where does all that methane come from?’ and biologists ignorant ‘Where all that methane goes’” “The biota and Gaia: 150 years of support for environmental sciences”, in S. H. Schneider et P. J. Boston eds. *Scientists on Gaia* (Cambridge: The MIT Press) p. 11–18.

<sup>15</sup> Latour, Bruno, “Why Gaia Is Not a God of Totality, Special Issue on Geosocial Formations and the Anthropocene.” *Theory, Culture and Society* 34, no. 2-3 (2017): 61-82.

<sup>16</sup> “I am an inventor. I find it easy to invent a self-regulating device by first imagining it as a mental picture. [...] In many ways Gaia, like an invention, is difficult to describe”. Lovelock, James, *Gaia. The Practical Science of Planetary Medicine*. (Gaia Books Limited, 2000): 11.

seems puzzling, it is actually essential to understand the shift he is trying to express.

Mechanistic explanations do not look at all the same when proposed by scientists or philosophers as a world view, and when it is used by inventors to describe the act of invention. It appears that inventors are well aware that no mechanism behaves in a mechanistic way when it is brought into the world. Something else is at work. Another mode where agency and history counts.<sup>17</sup> Lovelock's insistence on opposing engineering and academic science explains the ways he simultaneously multiplies, discards and then combines metaphors in order to approximate the originality of the phenomenon at work.

Although Gaia is often portrayed as a complex system, specifically as a complex adaptive system,<sup>18</sup> these are broad categories that fail to distinguish some of the unique features of Gaia. As an engineer-inventor, Lovelock naturally reaches for cybernetic language to describe the workings of Gaia, e.g. feedback, homeostasis, self-regulation, and optimisation.<sup>19</sup> But he equally reaches for biological language to describe the perceived entity and its functioning e.g. super-organism, geophysiology, whilst Margulis explicitly and repeatedly reminds him that Gaia is not an organism.<sup>20</sup> In addition, as a past medical researcher and someone with an extraordinary personal history of medical issues (and thus a great admiration for good doctors and nurses!) he is also drawn to physician's language when he speaks of "planetary medicine" even though he might dismiss such a comparison later.

The main point in this constant shuffling of images is to avoid the connection between a mechanism and the idea that there is a machine in the

traditional sense, that is, one built by some engineer situated *above* and in addition to the invention. Lovelock is at pains to make clear that Gaia is not a spaceship which would imply an engineer or a designer exterior to Gaia, a move that will immediately reaffirm the presence of some sort of purpose or teleology — not to say providential theology. This is why he constantly has to fumble with slightly contradictory images in order not to rely on any one of them.

What is crucial to understand, is that to combat the dangers of the mechanistic metaphor, neither Lovelock nor Margulis can rely on the main traditional alternative, that of organism. If the idea of a machine at the scale of the planet has no meaning — in case of a mechanical failure of the Earth system there is no Cape Kennedy and no Houston to turn to! — the absurdity is even greater if the notion of organism is inflated to the size of the Earth. No matter how tempting to lump all life forms in one huge, unified and continuous biosphere of some sort, or to invoke a superorganism, any idea of a giant composite planetary body should be resisted as much as the myth of the machine. Those who project onto Gaia the image of a global body, or even worse that of a female body, simplify too much Lovelock and Margulis' common project.<sup>21</sup> And it is sure they are not aware of Gaia's mythical pedigree. Any look at Hesiod will show that there is nothing maternal, womanly, or even godly in such a dangerous, archaic, cunning and chthonic figure that precedes all the gods.<sup>22</sup>

Even if Lovelock had succumbed to the metaphor of the organism, he would have been redressed by Margulis' own long fight against any idea of individual isolated life forms anyway. This is where the collaboration between the two co-inventors is so important and under-recognized. Not only does Margulis bring to the conceptual innovation a knowledge of biology and deep time Lovelock did not possess, but she makes impossible any use of a simplified version of an organism that could reside *inside* an environment that would be *exterior* to its history. Margulis' own discoveries and insights — a topic that has become more and more mainstream in recent years —<sup>23</sup>

make it impossible to separate any life form from its outside and impossible to take it as an atomic entity within its own distinct boundaries.<sup>24</sup>

“Holobionts” cannot be invoked to play the role of organisms submitted to a natural selection whose history would be forced upon them.

This is where the main difference with neo-darwinism lies and the reason why both discoverers of Gaia ran into trouble at first with so many biologists.<sup>25</sup> While Darwinian organisms don't have to create the situation in which they find themselves, Lovelockian agents have to take on their shoulders, so to speak, the task of bootstrapping the very “environment” in which they fold themselves. Natural selection for Lovelock appears as a simplified and on the whole local way to account for life forms’ engineering capacity whilst for Margulis it is not even a creative process but rather just the culling of ‘unfit’ variations.

To be sure, this constant shuffling of contradictory metaphors interfering with one another is confusing, but it’s not a reason to dismiss the theory or to freeze frame on one of the many images the authors proposed. It just means that Lovelock and Margulis have been struggling to find the right way to approach a unique phenomenon they were the first to focus on so directly because of the new historical situation in which they, and the rest of the planet, were embarked.<sup>26</sup> To do so, they had no other way than to make use of all means available, just as other scientists have done when faced with the problem of describing a major paradigm shift.

Actually, this offers a clear parallel with Galileo’s fumbling with metaphors to make sense of another totally unique situation, his way of handling falling bodies, namely the mechanistic way. Interestingly, both authors are positioned one at the beginning and the other at the end of the same arc of history.<sup>27</sup> These hesitations prove that in the same way that it is

difficult to invent Galilean objects, it is just as hard to dis-invent them in order to repopulate the Earth with what could be called Lovelockian or Margulisian agents.

### Why Gaia is not an organism

Retrospectively, and given the explosion of new knowledge available from Earth system science, it is no wonder that none of the usual metaphors could work. It is clear today that Gaia could not possibly have been considered to be an organism for at least three reasons.

The first is the level of exterior resources it depends on to survive. If Gaia is clearly not like an animal, it's because animals are *heterotrophs*, meaning that they feed on organic matter, whether alive or dead. This is the reason why comparing Gaia to literally *any kind of body*, be it the Earth “mother”, an animal or a “body politic”, cannot be anything but wildly inaccurate metaphors. In technical terms, Gaia is *autotrophic*, meaning that it makes itself out of inorganic materials, or more accurately *photoautotrophic* since it is powered by sunlight. However, Gaia cannot be compared to a plant, or alga or cyanobacterium, because those are open systems meaning that they continually exchange matter and energy with their surroundings. In contrast, Gaia is nearly *a materially closed system*, with minimal matter exchanges with the inner Earth and with space, and a vast degree of internal recycling.<sup>28</sup>

This is another difference with the Darwinian formulation of nature where organisms are continually interacting with other organisms in their environment, as well as continually exchanging materials with their outside. Gaia is not interacting with other Gaias. While any organism has an environment, strictly speaking Gaia *has no environment* except itself, if by environment we mean what with which any entity engages in a reciprocal relation. To be sure, the rest of nature can be said to reside “around Gaia” but only from an astronomical point of view of someone residing in outer space. Viewed from the inside of Gaia, the rest of the universe is simply *beyond* the outer limits of its system. Properly speaking, Gaia resides inside itself.

The second reason why Gaia cannot be compared to an organism, is that it has no homogeneous internal milieu. In other words, not only does it not have an outside, *it does not have a coherent inside either!* It is that sort of heterogeneity in the many cycles that have been discovered over the years that make the idea of a homogeneous biosphere so misleading. Shylock was sure of killing Antonio by carving “a pound of flesh”, but Gaia does not have

---

<sup>28</sup> Volk, Tyler. *Gaia's Body: Toward a Physiology of Earth* (New York: Springer-Verlag, 1998) is perhaps the most comprehensive source on this point.

such a unity that extracting a “pound of life” would kill the whole. It has no whole in a way an animal body is whole. This is what makes the question of deciding if it is alive or not especially moot and why it does not make much sense to defend or to attack the statement that “the Earth is alive”.

The question of what is alive and what is not in Gaia is so hard to pin point that some solid mineral forms are directly produced by life (bio-mineralisation), some are indirectly due to life because they rely on the oxygenation of the atmosphere, and some are fully abiotic. Similarly, some gases are uniquely biogenic (e.g. isoprene, dimethyl sulphide), many others have their abundance massively altered by life, and some do not interact with life (noble gases). In other words, Gaia is very much a patchwork and not a unified domain, sphere, region or entity. Depending on which chemical cycle you consider, you will have to pass through a long chain of living forms or none at all.<sup>29</sup>

The main point is to understand that in Gaia, the cycling of materials by the intermediary of life forms will vary enormously depending on their biological function (or lack of it). For the six most important elements for life (Carbon, Hydrogen, Nitrogen, Oxygen, Phosphorus, Sulfur), most of the matter being cycled has passed through a life form, in some cases many times. For other biologically essential elements, the intensity of cycling will vary, to use an economic metaphor, according to the balance between the demand made by life forms and the supply of non-living elements. Even in cases when the aggregate requirement of all life is much less than the physical and chemical supply (e.g. Iron or Silicon from weathering and erosion which are aplenty), there is still interesting control of the bio-available form. In general, the more we discover about biochemistry, the more the list of elements for which there is *no biological requirement* is dwindling. For those still on that list they are not generally cycled through life except by accident. This is the case for unreactive elements (e.g. noble gases), for which there is no cycling at all. So this nuance of different degrees and types of cycling does not fit a monolithic conception of Gaia.

The third reason why Gaia is not an organism is due to the disconnect between the immense amount of energy falling on Earth that activates its enormous machinery and the tiny but distributed amount that life forms

---

<sup>29</sup> For a general overview Lenton, Tim, and Andrew Watson, *Revolutions That Made the Earth*. (Oxford: Oxford University Press, 2011) and for more specialized references see e.g. Lenton, Timothy M. and Stuart J. Daines, “Biogeochemical transformations in the history of the ocean.” *Annual Review of Marine Science* 9 (2017): 31-58 and Lenton, Timothy M. and Stuart J. Daines, “Matworld – the biogeochemical effects of early life on land.” *New Phytologist* 215, no. 2 (2017): 531-537.

have been able to piggy back on. We always tend to forget that only a small fraction of the total energy (electromagnetic radiation) being absorbed at or near the Earth's surface and powering the climate is captured by a life form and converted to electrochemical form (although in parts of the visible spectrum the fraction captured by life is significant). This energy flux into life is readily dwarfed by the energy fluxes of the great heat engines of the atmosphere and ocean. The Earth absorbs roughly 120 petawatts of solar radiation, and for instance, the heat flux carried by the Gulf stream alone is approaching 1 petawatt, that is an order of magnitude bigger than the roughly 0.1 petawatt captured by life forms!

Nevertheless, living agents use this tiny fraction of the free energy flux to extraordinary effect, creating material cycles, altering the chemical composition of the atmosphere, creating aerosols and cloud condensation nuclei, and thus profoundly affecting the energy balance of the planet and the climate. This suggests that the particular utilisation of free energy by life, notably in information storage and processing, gives it unusual agency relative to abiotic climate processes. In a way, we should consider that Gaia is folded, distributed, inserted inside an Earth system that existed long before its development and will persist long after its demise, and that it has learned to modify but only partially. The result of this disconnect is to render any portrait of Gaia difficult to stabilize: if you look at energy transfer, life is barely visible; but if you look at the amount of new information and the fluxes of key biological elements, it is everywhere and has modified the whole system —except it is not a “whole system”!

Those three sets of scientific facts are what makes the uniqueness of Gaia so difficult to portray. Far from looking like a biosphere added to other spheres, Gaia appears as a reticular, lacunar, dappled, distributed sort of entity for which there is no precedent, nor comparison possible. The allusion we made above about a negative or apophatic way of portraying Gaia is clearly not a cop out: it is the only way to tackle at first what the topic requires. And that explains why Lovelock had to resort so often to a somewhat mysterious way of speaking of Gaia as a non-linear *sui generis* invention — a solution that had the unfortunate consequence of nurturing a magical “soft” view of a mystical Gaia very far from the hard-nosed fully reductionist view of science that Lovelock was also pursuing. Lovelock and Margulis did not over-animate a dead earth for some mystical reason; they simply refused, for strictly scientific reasons, to de-animate it, that is, to deny the agency of life forms.<sup>30</sup> Although it's true that Gaia requires special effort

---

<sup>30</sup> That Gaia, for this reason, is the first fully secular and non-providential figure of life, is argued in *Latour Facing Gaia* chapter 3 and 4.

from science, neither of them entertained the idea of an alternative more intuitive and superior “Gaian science”.

### There is one Gaia but Gaia is not one

The difficulty of approaching the uniqueness of Gaia is not only visible when one considers the many heterogeneous ingredients mobilised by its cycles, but also when the bewildering heterogeneity of the processes responsible for those cycles is taken into account. This is a point that was not so clear in the seventies but that has been highlighted more and more by the various results coming from Earth System Science. In all of the discussions about Gaia to reject or to embrace it too quickly, it was always implied that it had a wholeness and an integrity it did not in fact possess. While those could have been adjectives applied to “nature”, they don’t work for Gaia. Or rather, wholeness and integrity are exactly the key question implied by older philosophies of nature and thrown into doubt by the discovery of Gaia.

One could object that if such a wide distribution of mechanisms is true, what is the sense of invoking the name of “Gaia” at all and to give it, simply through the use of a personal name, some sort of unified character? But this would again be a way to skip what the discovery is about: even though life forms are not submitted to a frame that would be superior to them, they do produce such a frame, or more exactly, they generate as many frames as their intertwined history has locally produced. In other words, the reason why any notion of “whole” has to be put into question, is because life forms produce their own extension in space and time. If there is one case where one should not imply any *a priori* form of space and time, it is to follow the ways life forms extend and last. A Kantian view of space and time is not applicable to Gaia.

That Gaia makes its own (changing) boundaries in space and time is shown by the fact that the spatial extent of life’s influence has changed over time, reaching further down into the Earth’s crust and further up into the atmosphere.<sup>31</sup> Furthermore, the temporal extent of life’s influence is internally determined – by altering its own survival probability or collective persistence – to the extent that some studies suggest an Earth that had never had life would have undergone the runaway greenhouse fate of Venus by

---

<sup>31</sup> Norman H. Sleep, Dennis K. Bird, and Emily Pope, “Paleontology of Earth’s Mantle,” *Annual Review of Earth Planetary Science* 40 (2012): 277–300: “life has had a profound effect on surface geological processes, and even on modulated tectonics and the rise of continents. . . . The net effect is Gaian (Lovelock 1979); that is, life has modified Earth to its net advantage” (293) (we thank Bruce Clarke for this reference).

now, that is, would have left what astrophysicists describes as the ‘habitable zone’ around the Sun, where liquid water is present.<sup>32</sup>

In a different sense, the spatial boundaries of Gaia are somewhat dependent on the temporal scale of consideration. Thus, when considering the short-term response to perturbations such as human fossil fuel burning, only interactions between the atmosphere, ocean and life matter, but when considering the longer-timescale response to perturbations we have to consider exchanges with the crust and sedimentary rocks. When considering the response to geological drivers and the slow brightening of the sun on geological timescales, we also consider cycling of materials through sedimentary rock reservoirs in the crust.

**Table: Items defined by the test: biotic / abiotic planet**

Quality/property/process	Abiotic planet	Biotic planet
Energy	Ocean-atmosphere circulation is a heat engine	Photoautotrophy captures a small fraction of free energy but uses it to transform matter
Information	Minimal information content and abiotic processing	Massive storage and processing in biosphere
Bio-essential matter	Minimal cycling by physical and chemical processes	Massive (re)cycling of C, H, N, O, P, S and other essential elements by life
Other matter	Minimal cycling by physical and chemical processes	Minimal cycling by physical and chemical processes
Natural selection	No	Yes
Ecological sorting (niche construction, ecosystem engineering, community assembly)	No	Yes
Sequential selection (of stable configurations)	Maybe, but only in a crude way and not for habitable attractors	Yes, for habitable attractors
Selection by survival	No, because no means of acquiring new persistence-enhancing properties	Yes, biological innovation can generate new persistence enhancing properties

To capture these important aspects, we need to *break apart the unity and homogeneity of Gaia*. We need to somehow capture that Gaia is a heterogeneous phenomenon created by the actions and interactions of

<sup>32</sup> Lenton, Timothy, and Werner Von Bloh, "Biotic Feedback Extends the Life Span of the Biosphere." *Geophysical Research Letters* 28, no. 9 (2001): 1715-18.

many diverse biological free agents and aspects of their abiotic world, the result of which is a risky and provisional extension in space and a duration in time.

Paradoxically, although, as we noticed above, Earth system is often taken as a synonym of Gaia, Gaia is distinct from the Earth system and not strictly speaking a system —certainly not *one* system. As we underlined earlier this is why the concept of Gaia is distinct from the concept of Earth system which grew out of it. While ESS remains as close as possible to physics and chemistry, Gaia absorbs as much of biology and ecology as possible. It is as if the second was folded into the first in multiple ways. Although Earth system can be defined and described in terms of a Carnot heat engine, Gaia cannot because it continually creates its own domain and behaviour through information and evolution, that is, some sort of learning. What is observable is only the relative success of life forms in extending in space and lasting slightly longer in time. No more and no less. There is no guarantee of its continuity — no destiny superior to that of the life forms themselves. In a parody of Hutton we could say that in Gaia “we find many vestiges of a beginning and many prospects of an end”.<sup>33</sup>

The best way to understand this lack of unity is to consider that Gaia is a heterarchy with variations in the strength of coupling between the living and non-living across spatial and temporal scales and across different features (e.g. nutrient cycling, climate). A look at figure 1 will show the vast diversity of mechanisms depending on the scale of time and space.<sup>34</sup>

It is clear that there are variations in the type and strength of selection mechanisms that can arrive at and refine properties such as cycling and stability at different time and space scales. Nutrient (re)cycling is particularly strong at localised scales (for example within a forest) and can be understood as refined and reinforced by forms of conventional natural selection. Natural selection has also refined an amazing level of homeostasis for some organisms (e.g. human body temperature regulation), but such homeostasis is not detectable at the same level of coupling, at other scales. In contrast, global climate on long timescales appears less strongly regulated because it is understood to have arisen by simpler mechanisms. First it is a

simple principle that fragile incarnations (in this case of the coupling between living things and the climate) are fleeting but stable configurations, when found, tend to persist (termed 'sequential selection' in Table 1 and Figure 1). Second, that very persistence, combined with the incessant innovation accompanying the evolution of living agents, gives a greater chance of acquiring further persistence-enhancing properties (termed 'selection by survival' in Table 1 and Figure 1).<sup>35</sup>

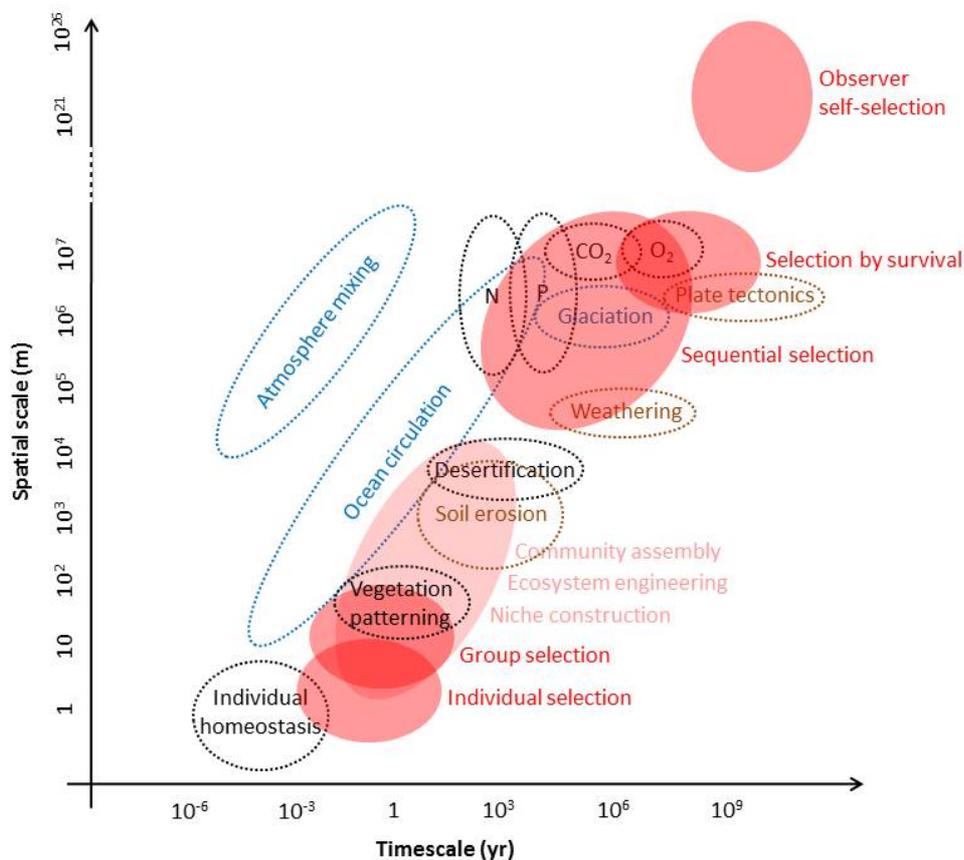

Figure 1: Space and timescales of Earth and Gaia processes. Some key Earth system processes are shown in blue (ocean-atmosphere) and brown (ocean-lithosphere). Examples of feedback mechanisms and regulated variables are shown in black. Selection and self-organisation mechanisms are shown in red.

This is not the place to develop the argument, but it is clear that no understanding of Gaia is possible without breaking down its spurious unity and making clear which one of the many phenomena composing it are

<sup>35</sup> Doolittle, W. Ford, "Darwinizing Gaia." *Journal of Theoretical Biology* 434 (2017): 11-19.

pointed at. We argue that if so many people have misunderstood Gaia, it's because they have chosen one scale and generalized to all the others. Such a multiplicity of processes cannot be lumped into one coherent entity even though some coupling provides some sort of overall order. It is this contradiction that is at heart of Lovelock's and Margulis discovery since day one: *there is one Gaia but Gaia is not "a whole"*.

It is in this sense that the notion of Gaia is so different from that of nature. When Earth was understood as a set of Galilean objects obeying laws of nature, it had a consistency, a homogeneity, a continuity, that Gaia entirely lacks. The domain of necessity that could be opposed to that of freedom was entirely made up of Galilean objects generating what was called by Descartes "*res extensa*". But if you try to compose the planet out of Lovelockian or Margulisian agents, it has a completely different feel. When scholars attempt at opposing "life" meaning biological life with "life" meaning moral and social *human* life, they imply a form of unity and of continuity fitting for the idea of "nature" but ill-adapted to the specificity of Gaia.<sup>36</sup> In consequence, human agents don't have the same role to play whether they reside "in nature" or if they see themselves as participating in Gaia. This is where the notions of order and regulation take a different political meaning.

### The tyranny of the Globe

In our view, this new conception of Gaia should modify political concepts on both sides of the older division between nature and society. Unfortunately, the traffic of images between biology and politics has been going on for so long that it is very difficult to extricate from its embrace a unique phenomenon such as Gaia.<sup>37</sup>

If it is so difficult to focus on Gaia, it is especially because any appraisal of a body in an environment is immediately confused with, not to say kidnapped by, the metaphor of the Globe. And it is true that when you pretend to consider Gaia "as a whole" you immediately summon the image of the Blue Planet viewed from out of space — in addition to an ample

---

<sup>36</sup> "Zoe" and "bios" in the confusing idiom resurrected by Dipesh Chakrabarty "The Human Condition in the Anthropocene" in *The Tanner Lectures on Human Values*, edited by Mark Matheson, (Salt Lake City University of Utah Press, 2016) pp.137-188.

(London: Palgrave, 2010); Fox-Keller, Evelyn. *Making Sense of Life: Explaining Biological Development with Models, Metaphors, and Machines*. (Cambridge, Mass: Harvard University Press, 2003).

circular gesture of the two hands! But no matter how powerful the influence of such an iconic photography, no matter how often you agitate your hands, the impulse to globalize should be resisted since none of those who claim to have “a global view” actually reside in *any real space*. They imagine themselves as if they were looking from the outside at the Earth taken as one body among all celestial bodies, just as Galileo did. The Global view is strictly speaking a view *from nowhere* — or from an office looking at a computer screen!

The difficulty of abandoning such a position is compounded by the confusion made between the cartographic globe and the rich artistic repertoire of older symbols of ancient Roman and Christian dominion.<sup>38</sup> The symbol of *orbis terrarum* held by the Emperor or by God is certainly not the best way to recognize the limited, entangled, highly complex and lacunar forms of Gaia. In addition, and to render the situation even more inextricable, any allusion to the Global is immediately fused with a social and political metaphor of the Body Politic. To see the polity as a big organism made of parts obeying the dictates of the whole, will be conjured at once in every description of order and system.

To combat such confusion, we should recognize that Gaia is not a globe at all but a thin biofilm, a surface, a pellicle, no more than a few kilometres thick that has not made inroads very far up in the atmosphere nor very far down in the deep earth below no matter how long you consider the history of life forms. This is why it is important to shift from the global vision of Gaia to what some scientists now call the *critical zone*.<sup>39</sup> Such a critical zone, because it does not have any way of being summed up in one classical image of the Globe, resists being immediately fused with a view of the planet viewed from the outside.<sup>40</sup> What Galileo had succeeded in doing — the Earth is just one body among all the other bodies of the infinite universe — the critical zone breaks down: Gaia requires to occupy a new situation for the observer as well as for what is observed. In addition, the great advantage of the critical zone is that it does not fit at all in any metaphor of the *orbis terrarum* held in the hand of a God, a Prince or an Emperor. There is no dominion to be exerted at all when the idea of Gaia as a thin biofilm is introduced into the

picture! Nothing rules anymore *above* the life forms. It's in that sense that we propose to say that those life forms literally *make their own laws*.

This is why it is so important to extract Gaia from being immediately lumped with a social and political idea of the Body Politic.<sup>41</sup> The reason is again that the metaphors of organism and superorganisms have been used to solve the question of the relations between parts and whole, that is, to distinguish a frame from what is being framed just as much in biology as in sociology.<sup>42</sup> To talk of Gaia as one organism is to suggest that they are, on one level, parts and, *on another level*, some whole that has distributed roles and functions to the parts. This is what is called the *organicist* view beautifully summarized in the *Fable of the Members and the Stomach*.<sup>43</sup> The idea that there are two levels, does not change much when you suggest that the parts, defined as so many individual agents, once they interact, generate what is called “emergent properties”, a metaphor summarized admirably in Mandeville’s *Fable of the Bees*, and associated with a “liberal” view. Although the two sets of images seem very different politically, they actually obey exactly the same pattern since they resort to two levels. In both cases — in both fables! — there is a whole superior to the parts, either a whole *before* in the organicist view or a whole *after* the interaction of the agents in the liberal view.

The problem is that those ubiquitous metaphor amalgamating social, physical, political, economic and biological visions, break down when applied to Gaia. And this is again where the Lovelock and Margulis collaboration is so important: the idea of parts and whole does not make much sense in Margulis’ definition of holobionts — indeed in any definition of life forms since every element is simultaneously the whole and a part of the whole—<sup>44</sup>. For Gaia, to speak of a system above and beyond the parts has no sense — no matter if you use a mechanical, cybernetic or biological metaphor — and to appeal to the notion of “emergent properties” so as to cross the distance between the levels of the parts and the level of the whole would be a cop out.

In the same way as Gaia is autotrophic, it is also a phenomenon *sui generis*, that is, it generates itself in a unique *ad hoc* way. That we have no good concepts to describe this situation is a proof that we relied too much on the usual repertoire coming from older amalgamation of political and biological order. To extricate Gaia out of such history, we should find a way to say that the whole is nothing above the parts but is *in continuity* with the parts — the word “part” being a way to name rather clumsily how elements are overlapping with one another.<sup>45</sup> This is what was true in the earlier somewhat romantic descriptions of Gaia “as a whole”. It’s true that it cannot strictly be composed of parts sitting, as philosophers says *partes extra partes*, side by side, just like Galilean objects used to do, waiting to be framed, explained, moved, possessed by laws of nature. It does not mean that “everything is connected”, but that Lovelockian agents have different ways of being intertwined. It is in that sense that Lovelock and Margulis’ discovery of Gaia should play havoc on the age-old commerce between social and biological metaphors. The “sociobiology” of Gaia could not be the same as the “sociobiology” based on earlier definitions of the natural world.

#### Conclusion: an extension of the domain of freedom

After this attempt at portraying Gaia by what it cannot possibly be (the apophatic way), we might have shed light on Lovelock’s sentence chosen as the epigraph: “The Gaia hypothesis implies that the stable state of our planet includes man as part of, or partner in, a very democratic entity.” At first sight, it might seem counterintuitive to expect a lesson on democracy from an author known for his contrarian and even reactionary views on a number of issues regarding human politics. However, what we are interested in are his contributions to what could be called the politics of *non-humans*.

The uniqueness of Gaia opens a new definition of what is a polity just at the time when the situation summarized by the term Anthropocene reopens the connection between what philosophers used to call the *domain of necessity* — that is, nature — and the *domain of freedom* — namely, politics and morality. It would be odd, indeed, not to consider the new climatic regime as an occasion to draw new connections between the two domains. Drawing lessons from nature to define the order and regulation of society has been going on for as long as political thought. The question raised by Lovelock and Margulis’ Gaia is to consider whether those lessons change when the two

<sup>45</sup> Tarde, Gabriel, *Monadology and Sociology* (Translated by Theo Lorenc). (Melbourne: Re.press, 2012 [1895]); Latour, Bruno, Pablo Jensen, Tommaso Venturini, Sébastien Grauwin, and Dominique Boullier. “‘The Whole Is Always Smaller Than Its Parts’ a Digital Test of Gabriel Tarde’s Monads”. *British Journal of Sociology* 63, no. 4 (2012): 591-615.

domains are being *symmetrically challenged*. Does it make a difference to draw lessons from nature or from Gaia?

If history is a good guide, the spectre of naturalization is sure to trigger in social scientists and those in the humanities a recoil of horror, and rightly so. It's enough to remember social Darwinism, sociobiology, dialectic materialism, the eugenicist movements, the IQ controversies, or for that matter much of economic science purporting to make human societies "obeys the laws of nature". Against those attempts at ordering and regulating humans in the name of nature's "iron cage", the domain of human freedom should be protected at all cost. On the other hand, the new climatic regime obliges us to revise such a reaction since the situation is now upside down: it is the Earth that has to be "protected at all cost" against the encroaching of human (dis)order and (de)regulation. So, the Anthropocene puts political philosophy in a double bind: we should not expect nature to dictate human behaviour and yet we can no longer abstain from drawing lessons from Earth behaviour because of the way it reacts to human behaviour. So far, discussions about the new political role human should play has not been able to escape from such a quandary.<sup>46</sup>

Since Lovelock's and Margulis' Gaia, in our rendering of their theory, grants agency and historicity to *all life forms*, the situation might now be opened again because it is cracked *on both sides* of the ancient dichotomy between necessity and freedom. That is the novelty to be addressed and the chance to be seized. When humans look at Gaia, they do not encounter the inflexible domain of necessity but, strangely enough, what is largely a domain of freedom, where life forms have, in some extraordinary ways, made their own laws, to the point of generating over eons multiple, heterogeneous, intricate and fragile ways of lasting longer in time and extending further in space. Nothing more, nothing less.

Conversely, any human trying to situate oneself as "part" or "participating" in this history can no longer be defined only as "free", but, on the contrary, as being *dependent* on the same sort of intricate and intertwined events revealed by Gaia. More freedom in the domain of necessity is fully matched by more necessity in the domain of freedom. This is what is meant by this extraordinary expression of "being partners in a very democratic entity". To play on Aristotle's famous saying, democracy is an expression designating an entity composed of all the "political animals", that is, all the beings, taken as people (*demos* in Greek) making their own laws and who do

---

<sup>46</sup> Hamilton, Clive. *Defiant Earth. The Fate of Humans in the Anthropocene*. (Cambridge: Polity Press, 2017).

not simply fall in any sort of preordained order or obey to any superior transcendent regulation.

It is for this reason that it is so important to define as exactly as possible the contribution made to this extended democracy by the discovery of Gaia: instead of replaying one more episode in the frustrating attempts at naturalizing human conduct, it opens the possibility of extending the domain of freedom by sharing it more widely on both sides. If such a view had been held by Roquentin in Sartre's canonical scene of *The Nausea*, he would not have vomited on the root of the tree, horrified by the totally senseless and superficial feeling of freedom he was condemned to by opposition with the equally senseless piece of wood. Nor do we propose that he feels suddenly some sort of effusion by becoming part and parcel of the evolution of trees. We just propose to suggest that they both share the feeling of freedom placing life forms at distance of one another but not the distance that used to paralyse humans and nature: the wary, puzzled, enigmatic and shifting distance politics have always entertained with one another.<sup>47</sup> One additional advantage would be to offer an alternative to the word "ecology" and to help scientists and activists to collaborate around what could be simply called *politics of life agents*.
